

Positional Talipes (TEV) exercise information

This leaflet is for parents whose baby has been diagnosed with positional talipes – known as TEV. It provides information on the exercises to be carried out to help correct this condition. If you have any questions or concerns, please speak to your physiotherapist.

What is TEV?

Positional talipes (equino-varus) is quite a common foot condition in newborn babies. It may affect one or both feet. It causes the foot to turn down and inwards when in the rested position but remains flexible (figure 1). Therefore, the foot can easily be moved into a normal position. It is thought to occur due to the baby's position in the mother's uterus. It will be diagnosed after an assessment by either a midwife or doctor. Gentle exercises to the foot will help it to come around into a normal position. It is important to carry them out regularly (for example with every nappy change).

Exercises should be carried out whilst your baby is relaxed and should never be forced or painful.

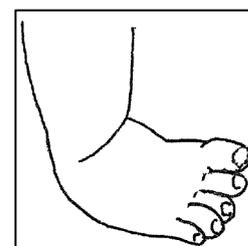

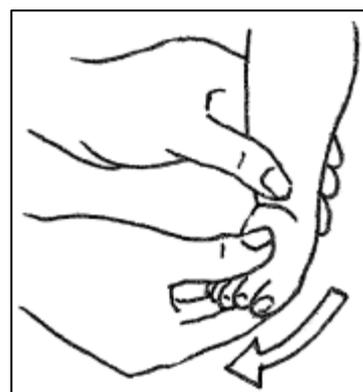

Figure 1

Exercise 1

Gently bring your baby's foot into the middle and then upwards towards their shin. This may be held for a few seconds, or longer if your baby lets you without showing signs of distress.

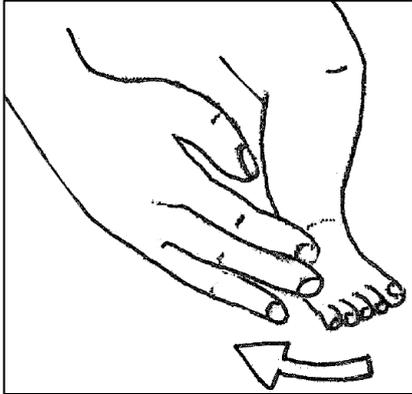

Exercise 2

Exercise 3

Gently stroke the outer border of your baby's foot and encourage the foot to move into a normal position.

Exercise 4

Positional talipes usually resolves with the exercises in the first few months. If you are concerned that the foot is stiff or not improving you should consult your child's GP.
